

Notes on the GSW code `gsw_z_from_p` for calculating height z from pressure p

Height z is measured positive upwards, so it is negative in the ocean. First, note that we use the following version of specific volume anomaly,

$$\delta = \hat{v}(S_A, \Theta, p) - \hat{v}(S_{SO}, 0^\circ\text{C}, p). \quad (1)$$

That is, the reference Absolute salinity is the Absolute Salinity of the Standard Ocean, $S_{SO} \equiv 35.165\,04 \text{ g km}^{-1}$, and the reference “temperature” is a fixed value of Conservative Temperature of zero degrees Celsius. Dynamic height anomaly is then defined by Eqn. (3.27.1) of IOC *et al.* (2010) as follows

$$\Psi = - \int_{P_0}^P \delta(p') dp', \quad (2)$$

where $P_0 = 101\,325 \text{ Pa}$ is the standard atmosphere pressure.

The vertical integral of the hydrostatic equation ($P_z = -g\rho$) is

$$\begin{aligned} \int_0^z g(z') dz &= - \int_{P_0}^P v(p') dp' = - \int_{P_0}^P \hat{v}(S_{SO}, 0^\circ\text{C}, p') dp' + \Psi \\ &= - \hat{h}(S_{SO}, 0^\circ\text{C}, p) + \Psi. \end{aligned} \quad (3)$$

We use the 25-term based expression (Eqn. A.30.6) for enthalpy, recognizing that because $\Theta = 0^\circ\text{C}$ many of the coefficients on pages 121-122 of the TEOS-10 Manual are zero, so the evaluation of Eqn. (A.30.6) is less computationally expensive than it may appear. Let us write the gravitational acceleration of Eqn. (D.3) of IOC *et al.* (2010) as

$$g = g(\phi, 0) (1 - \gamma z), \quad (4)$$

so that Eqn. (3) becomes

$$\boxed{\hat{h}^{25}(S_{SO}, 0^\circ\text{C}, p) + g(\phi, 0) \left(z - \frac{1}{2} \gamma z^2 \right) = \Psi}. \quad (5)$$

In the `gsw_z_from_p` code we ignore Ψ and solve this quadratic expression for the height z (using the standard quadratic solution equation, but for z^{-1} .) Note again that height z is negative in the ocean.

Notes on the GSW code `gsw_p_from_z` for calculating pressure p from height z

In the `gsw_p_from_z` code we evaluate pressure p using a modified Newton-Raphson iteration procedure so that the pressure so obtained is exactly consistent with the “forward” conversion of z from p via the function `gsw_z_from_p`.

A good starting point is the Saunders (1981) quadratic (note that the Saunders paper and the corresponding SeaWater code are for depth not height). So, given z we have a zeroth estimate of pressure, p_0 , from the Saunders (1981) quadratic expression. Now we want to solve

$$f(p) = 0, \quad \text{where} \quad f(p) = \hat{h}^{25}(S_{SO}, 0^\circ\text{C}, p) + g(\phi, 0) \left(z - \frac{1}{2} \gamma z^2 \right). \quad (6)$$

The derivative of $f(p)$ is

$$f'(p) = 10^4 \hat{v}^{25}(S_{SO}, 0^\circ\text{C}, p), \quad (7)$$

and this is available from appendix K of the TEOS-10 Manual (and since $\Theta = 0^\circ\text{C}$ $\hat{v}^{25}(S_{\text{SO}}, 0^\circ\text{C}, p)$ is particularly simple to evaluate, having only 10 terms, not 25). The factor of 10^4 in Eqn. (7) is because we want to solve for pressure in dbar rather than in the natural SI unit for pressure of Pa. That is, Eqn. (7) is the derivative of $f(p)$ with respect to pressure p in dbar.

Calculating $f(p)$ is computationally expensive, but calculating $f'(p)$ is cheap, so after finding p_0 we then evaluate $f(p_0) = \hat{h}^{25}(S_{\text{SO}}, 0^\circ\text{C}, p_0) + g(\phi, 0) \left(z - \frac{1}{2}\gamma z^2 \right)$, then calculate $f'(p_0) = 10^4 \hat{v}^{25}(S_{\text{SO}}, 0^\circ\text{C}, p_0)$ and use these values of $f(p_0)$ and $f'(p_0)$ to form an intermediate pressure estimate p_1 as

$$p_1 = p_0 - f(p_0)/f'(p_0) . \quad (8)$$

Then we form $p_m = 0.5(p_0 + p_1)$ and evaluate $f'(p_m) = 10^4 \hat{v}^{25}(S_{\text{SO}}, 0^\circ\text{C}, p_m)$ and use $f(p_0)$ and $f'(p_m)$ to get p_2 from

$$p_2 = p_0 - f(p_0)/f'(p_m) . \quad (9)$$

This is one full step of the “modified Newton-Raphson” iteration procedure and this one modified step gives pressure to better than 1.6×10^{-10} dbar (which is essentially machine precision) down to a height z of -8000m. The `gsw_p_from_z` function performs this one full iteration of the modified Newton-Raphson iteration.
