

## Notes on the function **gsw\_Nsquared(SA, CT, p, {lat})** which evaluates $N^2$ , the square of the buoyancy frequency

This function, **gsw\_Nsquared**(SA,CT,p,{lat}), evaluates  $N^2$ , the square of the buoyancy frequency, on a vertical cast using the 48-term expression for density,  $\hat{\rho}(S_A, \Theta, p)$ . The last argument, latitude, is optional. This 48-term rational function expression for density is discussed in McDougall *et al.* (2013) and in appendix A.30 and appendix K of the TEOS-10 Manual (IOC *et al.* (2010)). For dynamical oceanography we may take the 48-term rational function expression for density as essentially reflecting the full accuracy of TEOS-10.

This function, **gsw\_Nsquared**(SA,CT,p,{lat}), evaluates  $N^2$  from Eqn. (3.10.2) of the TEOS-10 Manual, that is, by using the equation

$$N^2 = g^2 \rho \frac{\beta^\Theta \Delta S_A - \alpha^\Theta \Delta \Theta}{\Delta P}$$

where  $\Delta S_A$  and  $\Delta \Theta$  are the differences between the Absolute Salinities and Conservative Temperatures of vertically adjacent seawater parcels separated in pressure by  $\Delta P$ , measured in Pa. The density  $\rho$  and the saline contraction and thermal expansion coefficients  $\beta^\Theta$  and  $\alpha^\Theta$  are evaluated at the average values of  $S_A$ ,  $\Theta$  and  $P$  of the two seawater parcels using the GSW Toolbox function **gsw\_rho\_alpha\_beta**(SA,CT,p). The gravitational acceleration  $g$  is found from the GSW Toolbox function **gsw\_grav**(lat, p) which is a function of latitude and of pressure in the ocean.

### 3.10 Buoyancy frequency

The square of the buoyancy frequency (sometimes called the Brunt-Väisälä frequency)  $N^2$  is given in terms of the vertical gradients of density and pressure, or in terms of the vertical gradients of Conservative Temperature and Absolute Salinity (or in terms of the vertical gradients of potential temperature and Absolute Salinity) by (the  $g$  on the left-hand side is the gravitational acceleration, and  $x$ ,  $y$  and  $z$  are the spatial Cartesian coordinates)

$$\begin{aligned} g^{-1}N^2 &= -\rho^{-1}\rho_z + \kappa P_z = -\rho^{-1}(\rho_z - P_z/c^2) \\ &= \alpha^\theta \theta_z - \beta^\theta \partial S_A / \partial z|_{x,y} \\ &= \alpha^\Theta \Theta_z - \beta^\Theta \partial S_A / \partial z|_{x,y}. \end{aligned} \quad (3.10.1)$$

For two seawater parcels separated by a small distance  $\Delta z$  in the vertical, an equally accurate method of calculating the buoyancy frequency is to bring both seawater parcels adiabatically and without exchange of matter to the average pressure and to calculate the difference in density of the two parcels after this change in pressure. In this way the potential density of the two seawater parcels are being compared at the same pressure. This common procedure calculates the buoyancy frequency  $N$  according to

$$N^2 = g(\alpha^\Theta \Theta_z - \beta^\Theta S_{A_z}) \approx -\frac{g}{\rho} \frac{\Delta \rho^\Theta}{\Delta z}, \quad \text{or} \quad N^2 = g^2 \rho (\beta^\Theta S_{A_p} - \alpha^\Theta \Theta_p) \approx \frac{g^2 \Delta \rho^\Theta}{\Delta P}, \quad (3.10.2)$$

where  $\Delta \rho^\Theta$  is the difference between the potential densities of the two seawater parcels with the reference pressure being the average of the two original pressures of the seawater parcels. Eqn. (3.10.2b) has made use of the hydrostatic relation  $P_z = -g\rho$ .
